## Conclusion

- Risk (Portfolio Variance) = Reward : Markowitz (1952)
- Variance != Reward : Haugen and Heins (1972), Campbell (1987), French et al. (1987), Golsten et al. (1993)
- Moreira and Muir (2017) - scaling month  $t+1$  investment in the market index by month  $t$  daily return variance
- Stock market return variance :  $SV_t = \sum_{m=1}^N \sum_{n=1}^N w_{m,t} w_{n,t} \text{COV}(r_{m,t}, r_{n,t})$
- Pollet and Wilson (2010) - decomposition of market variance into a compensated and uncompensated component
  - average variance (AV) :  $\bar{\sigma}_t^2 = \sum_{m=1}^N w_{m,t} \sigma_t^2$
  - average correlation (AC) :  $\bar{\rho}_t = \sum_{m=1}^N \sum_{n=1}^N w_{m,t} w_{n,t} \rho_{m,n,t}$
  - $SV_t \approx AV * \mathbf{AC}$  - Anadu and Tierens (2004)
  - $r_{t+1} = \alpha_1 + \beta_1 \mathbf{AC}_t + \epsilon_{1,t}$ ,  $\beta_1$  **positive and significant**
  - $r_{t+1} = \alpha_2 + \beta_2 AV_t + \epsilon_{2,t}$ ,  $\beta_2$  insignificant

## Conclusion

- If  $SV_t \approx AV \cdot AC$ , there maybe something to looking at AV and/or AC separately
- Moreira and Muir (2017) :  $\text{weight} = \frac{c_{SV}}{SV_t}$ , c is scaling factor to match buy and hold volatility
- Me :  $\text{weight} = \frac{c_{AV}}{AV_t}$ ,  $c_{AV}$  to match buy and hold volatility
- $SV_{t+1} = \alpha_3 + \beta_3 AV_t + \epsilon_{3,t}$ ,  $\beta_3$  positive and significant
- $AV_t$  management decreases investment when  $AV_t$  is high
- $AV_t$  management avoids decreasing investment when  $SV_t$  is high because AC is high
- Should find AV management outperforms SV management

Asset Results

## Conclusion

- Roll (1972) : relevant for time-series, variance-in-mean relation of stock market return
- Variance of observed returns  $\neq$  variance of "market" returns  $\neq$  variance of aggregate wealth
- Shocks to true market returns are positively related to the common observed component, AC
- AC is positively related to the covariance of stock market returns and aggregate wealth,  $cov(r_{s,t+1}, r_{u,t+1})$
- AV is not
- The relationships depend on the proportion of the true market observed,  $w_{s,t}$ , and the aggregate wealth  $\beta_t$  for the index
- [Details](#)
- [PW Return](#)

## Central Idea II

- If  $AC = \text{systematic}$ , when  $AC$  is high  $\Rightarrow$  higher  $r_{u,t+1}$  is expected
- $r_{u,t}$  is not observable through index returns
- Suggestive evidence is support of Pollet and Wilson (2010) relation
  - In a subset where daily returns are unrepresentative,  $AC$  won't predict  $r_{s,t+1}$ ,  $AV$  management won't perform
  - $AV$  management should work globally
  - Equity  $AV$  management has higher investment in times of higher  $cov(r_{s,t+1}, r_{u,t+1})$ , so it should work across asset classes

# US Equity Performance

Cummulative Excess Log Returns: Leverage - Unconstrained

AV : 9.68% SV : 8.60% BH : 5.93%

Notes: \*\*\*, \*\*, and \* Significant at the 1, 5, and 10 percent levels.

# Performance Summary

## Unconstrained

- Outperforms with higher returns for the same variance
- Outperforms with other risk specifications - downside, skewness, kurtosis,  $\alpha$

## Leverage

- As leverage constraints tighten AV outperforms SV
- AV and SV management outperforms the buy and hold - gains hedging (months  $< 1$ )
- SV needs more than 1500% leverage,  $AV \approx 300\%$
- AV management is cheaper and more practical

Conclusion

- CRSP daily returns contain only NYSE firms, are shallower, more illiquid, and investment was not a meaningful part of aggregate wealth 1926 - 1962 - NYSE (2016) and Taylor (2014)
- AC should not predict returns 1926 - 1962
- AV management should work globally
- AV management using the AV of equity returns should generate better performance across asset classes
- AV managed returns should depend systematically on the representativeness of daily returns

## Variance Management

- Moreira and Muir (2017) and Hocquard, Ng, and Papageorgiou (2013)
- AV is a better dynamic volatility management signal - returns, ratios, drawdowns, costs
- AV management works globally and across asset classes (SV does not)

## Risk Dynamics

- Gonzlez-Uribeaga and Rubio (2016) and Bollerslev, Hood, Huss, and Pedersen (2017)
- AV comes from the foundations of investment risk
- AV management informs about the risk mix across the economy

Global Results  
Asset Results

Conclusion

- Pollet and Wilson (2010) - AC is positively related to the correlation of market returns and aggregate wealth, including the unobserved component of the "true market"
- AC signal changes in systematic risk when the daily returns used are a good proxy for the "true market" and the market is a significant part of aggregate wealth.
- This is similar to the difference in results between Goyal and Santa Clara (2003) and Bali et al (2005) when the latter removes a significant number of daily returns and the forecasting ability of idiosyncratic volatility disappears
- Thus we can run a placebo-like test on a sub-sample where the daily returns are not representative

## Subsample Tests

- The CRSP daily return data contains only returns for assets traded on the New York Stock Exchange (NYSE) prior to 1962.
- The prior data is much shallower with fewer than 400 assets
- As much as 13% of market capitalization is not captured by CRSP data as of the 1950s.
- Twice as many firms covering twice as many industries are available at the end of 1962 as compared to the end of 1961.
- As shown in Taylor (2014) the NYSE market was not a significant part of marginal wealth in the US following the Great Depression before the late 1950s.

Asset Results

Conclusion

- Expect AC not to predict returns in the pre-1962 data but it should post-1962
- In-sample regression coefficients can be corrected for possible "volatility feedback" - Campbell and Hentschel (1992)
- Amihud and Hurvich (2004) - bias correction
- Omit variance ( $SV_{t+1}$ ) prediction by AV as it works in both sub-samples
- Goyal and Welch (2008) forecasting relationships maybe unstable and quite sensitive to sample period choice; they may not respond dynamically with the limited information available to investors in real-time and may not explain or support a trading strategy

## Return Prediction

- Asymptotically normally statistic comparing significance of accuracy ratio

## MSE-F Mcracken (2004)

- $MSE-F = T \times \frac{\frac{1}{T} \sum_1^T (e_{b,t}^2 - e_{x,t}^2)}{MSFE_x}$
- MSE-F = F-type test for significance in squared residual

## ENC-HLN Harvey, Lebourne and Newbold (1998)

- Optimal forecast =  $\hat{y}_t^* = (1 - \lambda)\hat{y}_{b,t} + \lambda\hat{y}_{x,t}$
- $\lambda$  = measure of the optimal combination of forecasts

## Diebold-Li and Mariano (2010)

## Out of Sample Results

Table: Sample 1939:12 to 2016:12

	DM	MSE-F	ENC-HLN
$AC_{t+1}$	1.604*	46.251***	1**
$SV_{t+1}$	1.041	21.57***	0.956**
$AV_{t+1}$	3.104***	198.267***	1***
$RET_{t+1}$	-2.027	-8.702	0

## Robust Out of Sample Results

Table: Sample 1939:12 to 2016:12

Stat	Variable	DM	ENC-HLN
$R_T$	$SV_{t+1}$	8.874***	1.838***
$R_T$	$RET_{t+1}$	29.124***	4.871***
$A_T$	$SV_{t+1}$	2.647***	0.949***
$A_T$	$RET_{t+1}$	13.347***	1.68***

Notes: \*\*\*, \*\*, and \* Significant at the 1, 5, and 10 percent levels.

- These results compare the use AV to SV in forecasting - not case either is good (RET) but AV is better

## Global Equity

- If AV management times investment to compensated risk because it changes in response to changes in systematic vs non-systematic risk it should work outside the US
- World AV and SV are market cap weighted averages of country values, US included

Conclusion

- If AV management times to changes systematic vs non-systematic risk, equity AV should provide a management signal for more than equities
- Moriera and Muir (2017) show that equity SV does not work as a signal for currency investment
- World AV and SV used with  $c$  calculated to match buy and hold for each index

Conclusion

- AV management is better than SV: higher returns, better ratios, lower costs
- AV management is better because it times moving in and out of investments to changes in systematic risk which is compensated and non-systematic risk which is not
- As such, AV management is a useful signal both globally and across assets classes where SV management does not perform
- Thank you

## More Pollet and Wilson (2010)

## PW Details

- Start with Campbell and Viceira (2002) :

$$r_{i,t+1} \approx \gamma \sigma_{i,m,t} - \frac{\sigma_{i,t}^2}{2}, \text{ m is true market}$$

- holds for  $i = s$ , stock market portfolio

- $r_{s,t+1} \approx \gamma \text{cov}_t(r_{s,t+1}, r_{m,t+1}) - \frac{\sigma_{s,t}^2}{2}$

- $r_{s,t+1} \approx \gamma \text{cov}_t(r_{s,t+1}, w_{s,t} r_{s,t+1} + (1 - w_{s,t}) r_{u,t+1}) - \frac{\sigma_{s,t}^2}{2}$ ,  
u is observable component

- $r_{s,t+1} \approx \gamma \text{cov}_t(r_{s,t+1}, w_{s,t} r_{s,t+1} + (1 - w_{s,t}) r_{u,t+1}) - \frac{\sigma_{s,t}^2}{2}$

- $r_{s,t+1} \approx \gamma w_{s,t} \text{var}_t(r_{s,t+1}) + \text{cov}(r_{s,t}, (1 - w_{s,t}) r_{u,t+1}) - \frac{\sigma_{s,t}^2}{2}$

## More Pollet and Wilson (2010)

- assume shocks to stock returns :  $\bar{\epsilon}_{z,t+1} + \epsilon_{i,t+1}$ ,  $z$  common i idiosyncratic
- $r_{s,t+1} = \beta_t r_{m,t} + \bar{\epsilon}_{z,t+1}$
- $\text{var}(\bar{\epsilon}_{z,t+1} + \epsilon_{i,t+1}) = \sigma_{z,t}^2 = \theta_t \sigma_{z,t}^2 + (1 - \theta_t) \sigma_{i,t}^2$ ,  $\theta$  common part
- $r_{u,t+1} = \frac{1-w_{s,t}\beta_t}{1-w_{s,t}} r_{m,t} - \frac{w_{s,t}\beta_t}{1-w_{s,t}}$
- substitute and simplify (many steps)
- $\text{cov}(r_{s,t}, r_{u,t+1}) = \frac{1-w_{s,t}\beta_t}{1-w_{s,t}} \frac{\bar{\sigma}_t^2}{\beta_t} \frac{\bar{\rho}_t - \theta_t}{1-\theta_t} \bar{\rho}_t - \frac{w_{s,t}\theta_t}{1-w_{s,t}} \frac{\bar{\sigma}_t^2}{\beta_t} \frac{1-\bar{\rho}_t}{1-\theta_t} \bar{\sigma}_t^2$
- more simplification
- $\text{cov}(r_{s,t}, r_{u,t+1}) = \pi_0 + \zeta_1 \bar{\rho}_t + \zeta_2 \bar{\sigma}_t^2$
- $\zeta_1$  positive but small for plausible values of  $w_{s,t}$  and  $\beta_t$ ,  $\zeta_2$  negative but small for plausible values
- [Return](#)
